#### **Abstract**

Zohreh River is one of the main water sources in south of Khuzestan, Iran. Due to importance of heavy metals on water quality, metal Index (MI), pollution Index (PI), heavy metal pollution index (HPI) and contamination index (Cd) were used to evaluate this River quality. For this purpose, water samples were collected during each season at 11 stations and seven heavy and trace metals [mercury (Hg), cadmium (Cd), chromium (Cr), manganese (Mn), nickel (Ni), lead (Pb) and zinc (Zn)] determined. Standard value for each metal were extracted from international standards [United States Environmental Protection Agency (EPA) and World Health Organization (WHO)] and some national guidelines (Iran, Iraq, Egypt, Jordan, Lebanon and India). Results showed that Hg, Cd, Cr, and Zn concentrations were below the highest permissible value using all suggested guidelines while other metals showed low to high values based on used guidelines at some stations. MI was in the range of 1.01-2.88, 0.75-2.29 and 1.91-8.03 during spring, summer and winter, respectively. High values of PI (3.03), HPI (803) and Cd (2.03) were found during spring (0.38), summer (75) and summer (-4.66), respectively. Comparison between selected indexes indicated that MI index showed normal values compared with other indexes. Also the guideline suggested by Lebanon revealed high quality for the River compared with other standards. Consequently, Zohreh River showed low quality for drinking uses during winter while the River showed high quality during other seasons.

Keywords: C Metal Index, Pollution Index, Water Quality

#### Introduction

Rivers from the ancient times have been the main water sources, especially in flat plain, so maintaining its quality is important. Anthropogenic influences degrade rivers (Carpenter et al., 1998; Jarvie et al., 1998). River pollution is one of the most important issues in developing countries, because maintenance of water quality did not developed with their growing (Sundaray et al., 2006; Karbassi et al., 2007; Akoto et al., 2008; Ahmad et al., 2010). Regarding to importance of this subject, many studies were conducted about it(Tayfur et al., 2008; Houben et al., 2009; Ketata et al., 2011).

Heavy metals like Hg, Cd, Cr and Pb are among the most common environmental pollutants, and their occurrence in waters and biota indicate the presence of natural or anthropogenic sources (Abdullah, 2013a). These pollutants were derived from urban and agricultural runoff, chemical fertilizers, pesticides and soil leaching (Hatje *et al.*, 1998; Amman *et al.*, 2002; Nouri *et al.*, 2006; Nouri *et al.*, 2008).

Trace metals (Mn, Ni and Zn) such as heavy metals have high pollution potential (Gueu *et al.*, 2007; Lee *et al.*,

2007; Adams *et al.*, 2008; Vinodhini and Narayanan, 2008). Although trace metal are essential as micronutrients for the life processes in animals and plants(Kar *et al.*, 2008; Suthar and Singh, 2008; Aktar *et al.*, 2010) but their accumulation in human body cause damage to body organs (Lee *et al.*, 2007; Lohani *et al.*, 2008). The concentration of the metals in unaffected environments is very low and is mostly derived from the mineralogy and the weathering (Karbassi *et al.*, 2008). The rivers have been polluted by these metals because of either natural or anthropogenic sources(Bem *et al.*, 2003; Wong *et al.*, 2003; Adaikpoh *et al.*, 2005; Akoto *et al.*, 2008). Heavy metal assessment have been the topics of interest for researchers like: Edet and Offiong (2002), Geriesh *et al.* (2004), El-Sayed (2008), Abdullah (2013a), Khalifa (2014) and Goher *et al.* (2014).

Zohreh River is one the most important rivers in Khuzestan, Iran, with a total length of nearly 275km. Today it is the source of drinking water supply for a great number of people especially in Kheriabad basin. Due to its importance, this study is to ascertain the concentration of heavy and trace metal in Zohreh River and assessment of the metal contamination using different indexes.

## **Materials and Methods**

The study area is situated between latitude of 30° 20'-30° 40' N and longitude 49° 47'-50° 15'E covering an area of about 5000 ha. Figure 1 shows location of the study area in Khuzestan province, Iran. Water samples were obtained from 11 stations (Table 1) which are shown in Figure 1. Sampling was divided into four-time consist of: Spring, Summer, Autumn and Winter. Then, samples were transported to the laboratory and were analyzed according to Iranian National Standard (ISIRI, 2005; ISIRI, 2010). The measured parameters include mercury (Hg), cadmium (Cd), chromium (Cr), manganese (Mn), nickle (Ni), lead (Pb) and zinc (Zn). River discharge in each sampling was also determined.

$$HPI = \frac{\sum_{i=1}^{n} Q_{i}W_{i}}{\sum_{i=1}^{n} W_{i}}$$

$$where:$$

$$Q_{i} = 100 \frac{V_{i}}{S_{i}}$$

$$W_{i} = \frac{k}{S_{i}}$$
(3)

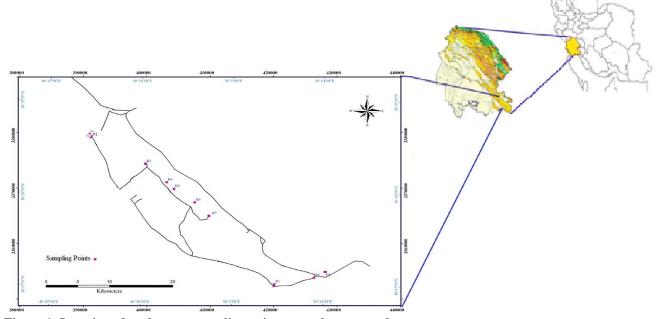

Figure 1: Location of study area, sampling points are ashown as red squares

In order to classify of Zohreh River, the metal index (MI), pollution index (PI), heavy metal pollution index (HPI) and contamination index (Cd) were applied (Edet and Offiong, 2002; Reza and Singh, 2010; Abdullah, 2013a). These indexes are shown in Equations 1-4, respectively:

$$MI = \sum_{i=1}^{n} \frac{C_i}{MAC_i}$$
 (1)

$$MI = \sum_{i=1}^{n} \frac{C_i}{MAC_i}$$
 (1)
$$PI = \frac{\sqrt{\left(\frac{C_i}{S_i}\right)_{\text{max}}^2 + \left(\frac{C_i}{S_i}\right)_{\text{min}}^2}}{2}$$
 (2)

$$Cd = \sum_{i=1}^{n} C_{fi}$$
 (4)

where:

$$C_{fi} = \frac{C_{Ai}}{C_{Ni}} - 1$$

Which  $C_i$  is mean concentration metal,  $MAC_i$  is maximum allowable concentration in µg.l  $^{1},S_{i}$  is recommended standard for the i<sup>th</sup> parameter in µg.1  $^{1}$ , $V_{i}$  is monitored value of the i<sup>th</sup> parameter in  $\mu$ g.1 $^{-1}$ ,k is the constant of proportionality,  $C_{Ai}$  is analytical value for the i<sup>th</sup> parameter in  $\mu g.1^{-1}$ ,  $C_{Ni}$  is upper permisible concentration of the i<sup>th</sup> parameter in  $\mu g.1^{-1}$ .

MI classified into six categories (Table 2). Generally, the critical pollution index value for HPI is 100 (Backan et al., 2010; Reza and Singh, 2010). PI categorized into 5 class (Table 3) and Cd grouped into 3 categories as follows: low (Cd <1), medium (Cd =1-3) and high (3<Cd) (Edet and Offiong, 2002; Goher et al., 2014).

3	2-3	Moderately affected
4	3-5	Strongly affected
5	>5	Seriously affected

Standard value for each parameter were extracted from EPA (2009), WHO (2011), drinking water standard of Iran (ISIRI), Iraq, Egypt, Jordan, Lebanon and India (IS 10500,

1993; WHO, 2006; Egyptian drinking water quality standards, 2007; Ministry of Planning and Development Cooperation, 2009; ISIRI, 2010). Minitab 16 software was used for determination of correlation coefficient (r) between the measured parameters.

## **Results and Discussion**

The standard deviation (SD), minimum (Min), maximum (Max) and mean value of individual metals for each season are represented in Table 4. Maximum and minimum variation were found in manganese (Mn) and mercury (Hg), respectively. Cd, Cr, Ni, Pb and Zn were varied in the range of 0.5-1, 2.5-5, 2.5-54, 2.5-45 and 1-122 µg.l<sup>-1</sup>, respectively. Hg concentration in each season was 0.5 µg.l<sup>-1</sup>. Maximum and minimum concentration of Ni were in winter and spring, respectively. Concentration of other parameter in autumn were not detected. Ni is positively correlated with Pb and Mn in winter and spring, respectively. Pb is also positively correlated with Zn during spring. There was no correlation between river discharge and the monitored metals.

The concentrations of Hg, Cd, Cr and Zn were found below the highest permissible value of the mentioned standards. While the concentration of Mn during winter were detected to be above the permissible value based on national standard of Iran (ISIRI), Egypt and Jordan except at three stations (P1, P3 and P4). P1 showed high Mn concentrations during spring and summer. There was also high Mn concentration in P3 during spring based on Iran, Egypt and Jordan national standard. The Ni concentrations were below the permissible value during spring and summer. Although concentration of Ni was recorded in the range of 5-54, it is below the critical value based on ISIRI and Jordan national standard. Pb concentrations were below the permissible value based on national standard of Egypt and Lebanon. Based on the other standards all stations during spring and summer and P1 during winter were below the critical value. The results showed that in the most of selected stations, water was found to be appropriate quality for drinking usage. It may be assigned to the purification of factories sewage before it is drained into the river.

MI values during spring for each stations are shown in Figure 2. Stations R1, R2, R4 and R7 were pure (0.3<MI<1). Similar results cited by Abdullah (2013b). Stations R3 and P1 were slightly (1<MI<2) and seriously (6<MI) affected, respectively. The results agreed with Amadi *et al.* (2012) about slightly affected of River Chanchaga. Other stations were moderately affected (2<MI<4).Similar results reported by Goher *et al.* (2014) for evaluating the pollution status of Ismailia Canal.

MI values obtained by EPA standard showed similar to ISIRI except at stations P1 (2.54) and P3 (1.44). It may be

<sup>\*</sup> ND: not detected

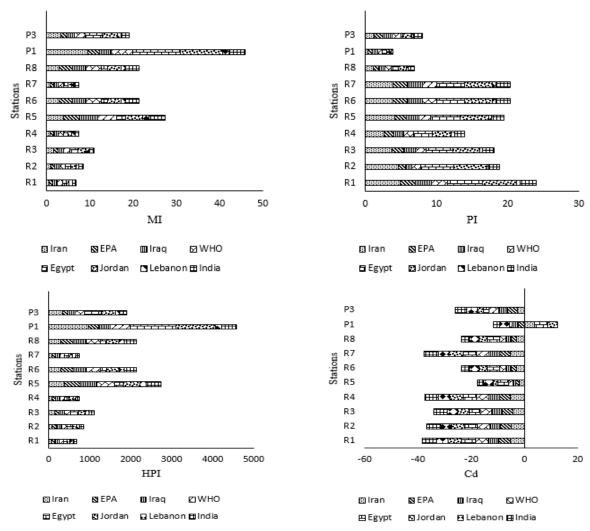

Figure 2: Comparison of four heavy metal indexes in spring

due to high Ni concentrations in mentioned stations. Although metals concentration at each station were different but limited value of Ni concentration according to ISIRI is 3.5 times more than EPA, which cause great differences between mentioned stations. Other standards

indicated different degree of pollution compared with ISIRI and EPA. Mean MI values of Zohreh River were 2.71, 1.82, 2.48, 2.09, 2.59, 2.88, 1.01, 2.00 based on ISIRI, EPA, WHO, Iraq, Egypt, Jordan, Lebanon and India standard,

respectively (Figure 3). The most high quality stations obtained by uses of Lebanon national standard.

PI was in the range of 0.33-4.82, 0.67-2.25, 0.67-2.25,

reported by Ameh and Akpah (2011) and Abdullah (2013a). The HPI for Zohreh River showed values between 101-288. Cd index showed slight pollution effect at some

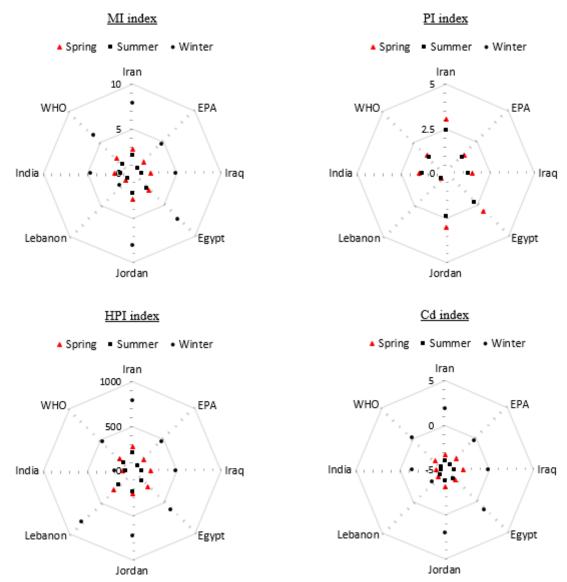

Figure 3: Mean value of each index during selected seaosons

0.67-2.25, 0.25-4.82, 0.33-4.82, 0.25-0.45 and 0.25-2.25 based on ISIRI, EPA, WHO, Iraq, Egypt, Jordan, Lebanon and India standard, respectively. It showed no effect to strongly affected at the stations. According to mean PI values, Lebanon standard (0.38) showed the highest quality of Zohreh River. The lowest quality obtained by using ISIRI and Jordan standard (3.03). HPI values were more than 100 using all guidelines which represented strong pollution effects at all stationsthat agreed with the results

stations. This index revealed high pollution effects at Station P1 using ISIRI, Egypt and Jordan standard. Mean Cd values were less than zero at all stations base on Figure 3.

Figure 4 illustrate the value of MI, PI, HPI and Cd for each station using eight guidelines during summer. MI values ranged between 0.60-10.57 using ISIRI. Based on Table 2 the stations P1 and R4 were seriously and

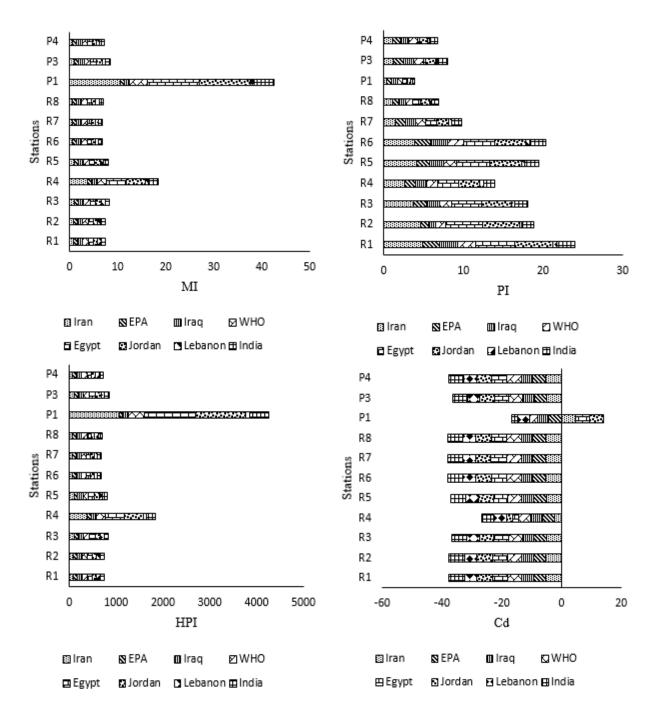

Figure 4: Comparison of four heavy metal indexes in summer

moderately affected, respectively. Other stations were pure. Comparison of other standards showed that MI values were pure based on EPA and Lebanon national standard. All stations were in the range of 1-2 based on WHO guideline except at station P1. The range of mean MI was 0.75

(Lebanon standard)-2.29 (Egypt standard).PI values ranged between 0.33-4.82 based on ISIRI. P1 had the lowest values among other stations. While station R1 recorded high value of PI. Mean values of PI were in between 0.34 (Lebanon standard)-2.41 (ISIRI and Jordan standard). Lebanon

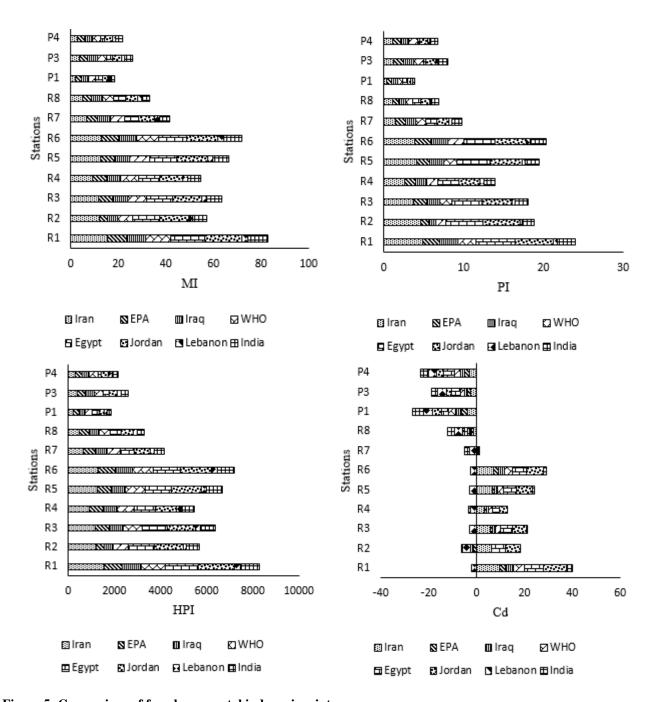

Figure 5: Comparison of four heavy metal indexes in winter

guideline showed PI values in the range of 0-1. It seemed Lebanon standard was the most conservative guideline among the others.

The HPI values was found to be above the critical value of 100 at all stations based on ISIRI. HPI values were 82 and 75 by using WHO and Lebanon guideline,

respectively. Other standards showed HPI values above 100. Station R4 and station P1 had minimum and maximum values of HPI, respectively. Cd index denoted negative values at many stations. Only station P1 indicated positive Cd (Cd>3) based on guideline suggested by ISIRI, Egypt and Jordan. Mean values of Cd index were negative which showed high quality of the River using all guidelines.

Soil Environ. 35(2): 161-170, 2016

MI, PI, HPI and Cd did not compute during autumn because of not detected metals in the season. Although these indexes were used to estimate the metal pollution during winter. MI index showed moderately affected at stations P1, P3 and P4 based on ISIRI (Figure 5). Station R8 was strongly affected according to MI. This index denoted seriously affected at other stations. This results were found in agreement with Lyulko et al. (2001), Caerio et al. (2005) and Abdullah (2013a).Lebanon standard showed the lowest mean value of MI (1.91), while the highest mean value of MI obtained by using Jordan standard (8.03). PI was in the range of 0.33-4.66, 0.67-2.05, 0.67-2.05, 0.67-2.05, 0.25-4.66, 0.33-4.66, 0.25-0.47 and 0.25-2.05 using guideline suggested by ISIRI, EPA, WHO, Iraq, Egypt, Jordan, Lebanon and India standard, respectively. Based on the mean values of PI index, Zohreh River showed the no effect (Lebanon standard), slightly affected (EPA, WHO, Iraq and India standard) and moderately affected (ISIRI, Egypt and Jordan standard). According to HPI index, all stations along the River showed high pollution for drinking usage. Cd index indicated the high pollution at stations R1, R2, R3, R4, R5 and R6 based on ISIRI (Cd>3). Cd index was in the range of -2.50-2.09, -2.20-2.39, -3.66—2.43 and -4.57-1.39 using guideline suggested by EPA, Iraq, Lebanon and India national standard, respectively. Other guidelines showed sligtht to strong pollution effects at the stations.

The results revealed that the mentioned indexes showed very different quality for Zohreh River. According to Cd values, all stations denoted high quality for the River but HPI values showed low quality. Zohreh River quality based on PI values had better quality than the River based on MI values. It may be attributed to the related equations. PI index consider only maximum and minimum proportionality for all metals. It seems cannot represent the effect of all metals on water quality. On the other hand, high concentration of any metals have great effect on PI values. In the case of MI index, there were lower values due to use the sum of all metals proportionality. On the other hand, HPI index uses a coefficient (Wi) at the numerator and denominator, which cause the value increases in comparison, when a simple ratio (V<sub>i</sub>/S<sub>i</sub>) uses. The concentrations ratio (C<sub>i</sub>/S<sub>i</sub>) change into negative value by using Cd index. Quality categories for Cd index also cause to reach high quality of the River.

#### Conclusion

According to the results, Hg, Cd, Cr, and Zn were found below the highest permissible value using all suggested guidelines while other metals showed low to highvalues based on used guidelines at some stations. Zohreh River quality was moderately, slightly, moderately

and slightly affected based on MI, PI, HPI and Cd values during spring, respectively. Results showed that Zohreh River quality was slightly affected based on MI, PI and Cd values during summer. HPI index revealed moderately affected of the River. MI, PI, HPI and Cd were moderately, slightly, strongly and moderately affected during winter. Zohreh River showed low quality during winter.It may be due to the precipitation and land erosion during winter (Ameh and Akpah, 2011) with respect to the "no correlation" between river discharge and the metals. The comparison between water quality using each metal and four metal pollution indexes (MI, PI, HPI and Cd) revealed that MI index showed normal values. Although PI index almost showed the same values but this index was sensitive to the minimum and maximum concentrations of the metals. Cd index indicated high quality for the River while HPI index showed low quality.
